A Class of Triple Error Correcting BCH Likes Codes

O.P.Vinocha, Ajay Kumar

Abstract - In a recent paper, Bracken and Helleseth [2009] showed that one can construct triple-error-correcting codes using zero set consisting different zero set than the BCH codes. In this correspondence we present some new triple error correcting code having zeros \([1, 2^k + 1, 2^k + 1] \) and \([1, 2^k + 1, 2^k + 1] \) where gcd \((2k, n) = 1 \) and \( n \) be odd.

Keywords: Triple error, Parity Check matrix & minimum distance.

I. INTRODUCTION

BCH codes [R.Bose and D.Ray-Chaudhuri, 1960] are of great practical importance for error-correction, particularly if the expected errors are small compared with the length. The BCH code is a subset of cyclic code. The binary primitive triple –error-correcting BCH code with minimum distance \(d = 7 \) is a cyclic code. We consider a finite field with \(2^n\) elements. \(g(x)\) be the generator polynomial of triple – error-correcting BCH code having \( \alpha, \alpha^2, \alpha^3 \) be its Zeros. The set \([1, 3, 5] \) is known as triple. Kasami showed that one can construct similar triple-error-correcting codes using zeros sets of different triples. Later Helleseth and Bracken presented some new triples and in addition they gave some new method for finding these triples. In this paper with the help of some new zeros we construct some triple-error-correcting BCH like codes.

Let \( H = \begin{bmatrix} 1 & \alpha^c_1 & \cdots & \alpha^{(2^n-2)c_1} \\ 1 & \alpha^c_2 & \cdots & \alpha^{(2^n-2)c_2} \\ 1 & \alpha^c_3 & \cdots & \alpha^{(2^n-2)c_3} \end{bmatrix} \) be the parity check Matrix of the triple error correcting BCH code where\(c_1 = 1, c_2 = 2 \) \& \( c_3 = 3\) the order of the matrix is \(3n\) by \(2^n – 1\). The code \( C = \{2^n – 1, 2^n – 3n – 1\} \) is a code of dimension \(2^n – 3n – 1\) and minimum distance \(d = 7\) between any pair of codewords. Generally we are interested in finding triples \(\{c_1, c_2, c_3\}\) s.t. \(H\) is the parity check matrix of a triple-error-correcting code.

II. PRELIMINARY NOTES

A well known result in coding theory for determining the minimum distance is that if there are no sets of \(d - 1\) linear dependent columns in \( H \) then the code \(C\) has distance at least \(d\). This fact is easily derived from the fact that \(C\) is the null space of \(H\). We will assume in this paper that \(H\) has six linearly dependent columns and derive a contradiction, which mean minimum distance is seven.

We know that the codes with zero sets \([1, 2^k + 1]\) where \(\gcd(k, n) = 1\) have minimum distance five. For \(k = 1\) this follows since the code is the double –error-correcting BCH codes.

The general result is consequence of the well known result \( f(x) = x^{2^k} + 1\) is an APN function when \(\gcd(k, n) = 1\).

Definition 2.1 An APN function is a function such that \(f(x+a) + f(x) = b\) has at most two solutions \(x\) is in \(GF(2^n)\) for any \(a \neq 0\) and \(b\) in \(GF(2^n)\). 

Theorem 2.2. The error-correcting code with zero set \([1, 2^k + 1, 2^k + 1]\) is triple error correcting provided \(\gcd(k, n) = 1\). 

Proof: proof is given in Carl Bracken and Tor Helleseth [2]

Theorem 2.3. Let \(n\) be odd and \(\gcd(k, n) = 1\). then the error-correcting codes constructed using zero set \([1, 2^{k} + 1, 23k+1]\) is triple – error-correcting.

Proof: proof is given in Carl Bracken and Tor Helleseth [2]

III. MAIN RESULTS

The zero sets considered by Helleseth and Bracken [1] are \([1, 2^k + 1, 2^k + 1]\) and \([1, 2^k + 1, 2^k + 1]\). We consider some new triple \([1, 2^k + 1, 2^k + 1]\) and \([1, 2^k + 1, 2^k + 1]\) where \(\gcd(2k, n) = 1\) and \(n\) is odd.

Theorem 3.1. The error-correcting code with zero set \([1, 2^k + 1, 2^k + 1]\) is a triple – error-correcting provided \(\gcd(2k, n) = 1\). For odd \(n\).

Proof: If \(H\) has six or less dependent columns then there must exist elements \(x, y, z, u, v, w\) in \(GF(2^n)\) s.t.

\[
\begin{align*}
&x + y + z + u + v + w = 0 \\
x^{2^k} + y^{2^k} + z^{2^k} + u^{2^k} + v^{2^k} + w^{2^k} = 0 \\
x^{2^k} + y^{2^k} + z^{2^k} + u^{2^k} + v^{2^k} + w^{2^k} = 0
\end{align*}
\]

The code with zero set \([1, 2^k + 1]\) with \(\gcd(2k, n) = 1\) has minimum distance 5. It follows first two equations that all elements \(x, y, z, u, v, w\) have to be different.

We can write this as \(x + y + z = a\)

\[
\begin{align*}
x^{2^k} + y^{2^k} + z^{2^k} &= b \\
x^{2^k} + y^{2^k} + z^{2^k} &= c
\end{align*}
\]

Replace \(x= x + a\), \(y= y + a\) and \(z= z + a\)

\[
\begin{align*}
x + y + z &= 0 \\
x^{2^k} + y^{2^k} + z^{2^k} &= b \\
x^{2^k} + y^{2^k} + z^{2^k} &= c
\end{align*}
\]

Where \(b = a^{2^k + 1} + 1\) and \(c = c + a^{2^k + 1}\) From (1) substituting \(z = x + y\),

Therefore equations (2) & (3) becomes

\[
\begin{align*}
x^{2^k} + y^{2^k} &= \beta \\
x^{2^k} + y^{2^k} &= \gamma
\end{align*}
\]

Replace \(y = x + y\) and we get

\[
\begin{align*}
x^{2^k} + (1 + y^{2^k}) &= \beta \\
x^{2^k} + (1 + y^{2^k}) &= \gamma
\end{align*}
\]

The above equations can be written as

\[
\begin{align*}
(y + y^{2^k}) &= \beta x^{-2^k -1} \\
(y + y^{2^k}) &= \gamma x^{-2^k -1}
\end{align*}
\]
A Class of Triple Error Correcting BCH Likes Codes

Equation (4) implies
\[ y + y^{2k} = \beta z^{2k} x^{2k}z^{-2k} + \beta x^{-2k} - 1 \]
Using above equation (5) becomes
\[ x^{2k+1} \left[ \beta z^{2k} x^{2k}z^{-2k} + \beta x^{-2k} - 1 \right] = \gamma \]
This becomes the Linearized equation
\[ \beta x^{2k} + \beta^{2k} x + y x^{2k} = 0 \]
As we know, \( \beta \neq 0 \) this implies by Lemma 1 the above equation has no more than four solution in \( x \) and we are done.

**Theorem 3.2** Then the code with zero set \( \{ 1, 2^{2k} + \lambda, 2^{2k} + 1, 2^{2k+1} \} \) is a triple – error correcting code where \( n \) be odd and \( \text{gcd}(2k, n)\) =1.

Proof: we use the same concept as we do in theorem 1 the system of equations are
\[ x^{2k+1} (y + y^{2k}) = \beta \]
\[ x^{2k} (y + y^{2k}) = \gamma \]
Where \( \beta = b + \alpha z^{2k+1} \) & \( \gamma = c + \alpha z^{2k+1} \)
From equation (1) implies
\[ y + y^{2k} = \beta x^{-2k} - 1 \]
\[ \Rightarrow y + y^{2k} = \beta z^{2k} x^{2k}z^{-2k} + \beta^{2k} x^{2k}z^{-2k} \]
Therefore equation (2) becomes
\[ x^{2k+1} (\beta z^{2k} x^{2k}z^{-2k} + \beta^{2k} x^{2k}z^{-2k} + \beta x^{-2k} - 1) = \gamma \]
\[ \Rightarrow \beta z^{2k} x^{2k}z^{-2k} + \beta^{2k} x^{2k}z^{-2k} + \beta x^{-2k} - 1 = \gamma \]
Put \( r = x^{2k+1} \) this substitution is 1-1
The Linearized equation is
\[ \beta r^{2k+1} + \beta^{2k} r + \gamma r + \beta^{2k} = 0 \]
Hence by Lemma 2 the above equation has at most three solutions in \( x \) and we are done.

3.1.0 Special properties
The following result can be found in C. Bracken, E. Byrne, N. Markin and G. Mc Guire, 2007

**Lemma 3.1.1** Let \( s \) be an integer satisfying \( \text{gcd} (2s, n) \) =1 and let \( f(x) = \sum_{i=0}^{d} r_i x^{2i} \) be a polynomial in GF \( (2^n) \), then \( f(x) \) has at most \( 2^s \) zeros in GF \( (2^n) \).

**Lemma 3.1.2**: An equation of the form \( x^{2k+1} + bx^{2k} + cx = d \) defined on GF \( (2^n) \). Has no more than three solutions in \( x \) when \( \text{gcd}(2k, n) \) =1 for all \( b, c \) and \( d \) in GF \( (2^n) \). The above lemma is consequence of result in A.W. Bluh

V. CONCLUSIONS

In this work we discussed a class of triple error correcting BCH like codes with the help of zero set is presented. This correspondence also gives some new connections to properties of some special equations of finite fields given in Lemmata 1 and Lemma 2. Finding further triple with different zero sets is a challenging research problem that may lead to other interesting connection?
