A Quantitative Study of the Automatic Speech Recognition Technique

Anchal Kaytal, Amanpreet Kaur

Abstract: In the last two decades, few researchers have worked for the development of Automatic Speech Recognition Systems for most of these languages in such a way that development of this technology can reach at par with the research work which has been done and is being done for the different languages in the rest of the world. Punjabi is the 10th most widely spoken language in the world for which no considerable work has been done in this area of automatic speech recognition. Being a member of Indo-Aryan languages family and a language rich in literature, Punjabi language deserves attention in this highly growing field of Automatic speech recognition. The Speech is most prominent & primary mode of Communication among human being. Today, speech technologies are commercially available for an unlimited but interesting range of tasks. These technologies enable machines to respond correctly and reliably to human voices, and provide useful and valuable services.

Keywords: ASR, Punjabi Speech Recognition, Recognition Techniques.

I. INTRODUCTION

Spoken language is not just a means to access information, but itself information. The speech is primary mode of communication among human being and also the most natural and efficient form of exchanging information among human in speech [1]. Speech Recognition can be defined as the process of converting speech signal to a sequence of words by means Algorithm implemented as a computer program. Communication among human beings is dominated by spoken language. Therefore, it is natural for people to expect speech interfaces with computers which can speak and recognize speech in native language. India has a linguistically rich area which has 18 constitutional languages, which are written in 10 different scripts [2].

Machine recognition of speech involves generating a sequence of words best matches the given speech signal. Some of known applications include virtual reality, Multimedia searches, auto-attendants, travel Information and reservation, translators, natural language understanding and many more Applications [3].

II. AUTOMATIC SPEECH RECOGNITION

Automatic speech recognition is the process of mapping an acoustic waveform into a text/the set of words which should be equivalent to the information being conveyed by the spoken words. This challenging field of research has almost made it possible to provide a PC which can perform as a stenographer, teach the students in their mother language and read the newspaper of reader’s choice. The advent and development of ASR in the last 6 decades has resolved the issues of the requirements of certain level of literacy, typing skill, some level of proficiency in English, reading the monitor by blind or partially blind people, use of computer by physically challenged people and good hand-eye co-ordination for using mouse. In addition to this support, ASR application areas are increasing in number day by day. Research in Automatic Speech Recognition has various open issues such as Small/ Medium/ Large vocabulary, Isolated/ Connected/Continuous speech, Speaker Dependent/ Independent and Environmental robustness [9].

A. Modules of ASR

Automatic speech recognition system is comprised of modules as shown in the figure.

Figure 2: Block Diagram of ASR System

Manuscript Received November, 2013.

1. Speech Signal acquisition: At this stage, Analog speech signal is acquired through a high quality, noiseless, unidirectional microphone in .wav format and converted to digital speech signal.

2. Feature Extraction: Feature extraction is a very important phase of ASR development during which a parsimonious sequence of feature vectors is computed so as to provide a compact representation of the given input signal. Speech analysis of the speech signal acts as first stage of Feature extraction process where raw features describing the envelope of power spectrum are generated. An extended feature vector composed of static and dynamic features is compiled in the second stage. Finally this feature vector is transformed into more compact and robust vector. Feature extraction, using MFCC, is the famous technique used for feature extraction.

3. Acoustic Modeling: Acoustic models are developed to link the observed features of the speech signals with the expected phonetics of the hypothesis word/sentence. For generating mapping between the basic speech units such as phones, tri-phones & syllables, a rigorous training is carried. During training, a pattern representative for the features of a class using one or more patterns corresponding to speech sounds of the same class.

4. Language & Lexical Modeling: Word ambiguity is an aspect which has to be handled carefully and acoustic model alone can’t handle it. For continuous speech, word boundaries are major issue. Language model is used to resolve both these issues. Generally ASR systems use the stochastic language models. These probabilities are to be trained from a corpus. Language accepts the various competitive hypotheses of words from the acoustic models and thereby generates a probability for each sequence of words. Lexical model provides the pronunciation of the words in the specified language and contains the mapping between words and phones. Generally a canonical pronunciation available in ordinary dictionaries is used. To handle the issue of variability, multiple pronunciation variants for each word are covered in the lexicon but with care. A G2P system- Grapheme to Phoneme Conversion is applied to better the performance the ASR system b predicting the pronunciation of words which are not found in the training data.

5. Model Adaptation: The purpose of performing adaptation is to minimize the system’s performance dependence on speaker’s voice, microphones, transmission channel and acoustic environment so that the generalization capability of the system can be enhanced. Language model adaptation is focused at how to select the model for specific domain. Adaptation process identifies the nature of domain and, thereby, selects the specified model.

6. Recognition: Recognition is a process where an unknown test pattern is compared with each sound class reference pattern and, thereby, a measure of similarity is computed. Two approaches are being used to match the patterns: First one is the Dynamic Time Warping based on the distance between the acoustic units and that of recognition. Second one is HMM based on the maximization of the occurrence probability between training and recognition units. To train the HMM and thereby to achieve good performance, a large, phonetically rich and balanced database is needed.

B. Data Preparation

1. Building Text Corpus: Text corpus means optimal set of textual words/sentences which will be recorded by the native speakers of a particular language. According to the domain specified for the ASR, the corresponding text is collected. Different context in which that text can be used, are also taken care of. Building a text corpus involves three steps: Text corpus collection, Grapheme to Phoneme Conversion, Optimal Text Selection.

2. Building Speech Corpus: With the help of Text Corpus, the recordings of selected words/sentences are done with the help of high quality microphones. During the development of speech corpus, information, which is generally noted down, is Personal Profile of Speakers, Technical details of microphone, Date and Time of Recording, Environmental conditions of recording. During the recording session, the parameters of the wave file to be set are: Sampling rate, Bit rate, Channel. Building Speech Corpus involves three steps: Selecting a speaker, Data Statistics, Transcription Correction.

3. Transcription File: A transcript file is required to represent what the speakers are saying in the audio file. It contains the dialogue of the speaker noted exactly in the same precise way as it has been recorded. There are two transcription files: one is meant for training the system and second one is meant for testing the system.

4. Pronunciation Dictionary: It is a language dictionary which contains mapping of each word to a sequence of sound units. The purpose of this file is to derive the sequence of sound units associated with each signal. The important point, which is to be taken care of while preparing this dictionary, the sound units must be contained in this dictionary, must be in ASCII.

5. Language Model: Language model is meant for providing the behaviour of the language. The language model describes the likelihood or the probability taken when a sequence or collection of words is seen. A language model is a probability distribution over the entire sentences/texts. The purpose of creating a language model is to narrow down the search space, constrain search and thereby to significantly improve recognition accuracy. Language model becomes very important when Continuous speech is considered. Speech recognizers seek the word sequence Ws which is most likely to be produced from acoustic evidence A as per the following formula:

\[
P (W_s | A) = \max_w P (W|A) = \max_w P (A|W) P (W)/P (A)
\]

A Quantitative Study of the Automatic Speech Recognition Technique

Figure 3: Block Diagram of Feature Extraction
Language Model assigns a probability estimate \( P(W) \) to word sequences \( W= \{W_1, W_2, \ldots, W_n\} \). These probabilities can be trained from a corpus. Perplexity is a parameter to evaluate language model. Suppose sentences in a test sample contains 2000 words and can be coded using 10000 bits then the perplexity of language model = \( 2^{(10000/2000)}=32 \) per word. Language model with low perplexity helps LM to perform well for the speech recognition system thereby compressing the test sample.

6. Filler Dictionary: It refers to a dictionary which contains the mapping of non-speech sounds to non-speech sound units.

\[ \text{e.g. } <\text{sil}> \text{ SIL} \]

C. Performance Parameters

Accuracy and Speed are the criterion for measuring the performance of an automatic speech recognition system which are described below:

1. **Accuracy Parameters**

   **Word Error Rate (WER):** The WER is calculated by comparing the test set to the computer-generated document and then counting the number of substitutions (S), deletions (D), and insertions (I) and dividing by the total number of words in the test set.

2. **Speed Parameter**

   Real Time Factor is parameter to evaluate speed of automatic speech recognition. Formula: \( S \frac{P}{I} \leq 1 \) where \( P \): Time taken to process an input Duration of input \( I \) e.g. RTF= 3 when it takes 6 hours of computation time to process a recording of duration 2 hours.

D. **Performance Degradation**

Automatic speech recognition suffers degradation in recognition performance due to following inevitable factors:

i. Prosodic and phonetic context
ii. Speaking behavior
iii. Accent & Dialect
iv. Transducer variability and distortions
v. Adverse speaking conditions
vi. Pronunciation
vii. Transmission channel variability and distortions
viii. Noisy acoustic environment
ix. Vocabulary Size and domain

III. AUTOMATIC SPEECH RECOGNITION CLASSIFICATION

The following tree structure emphasizes the speech processing applications. Depending on the chosen criterion, Automatic Speech Recognition systems can be classified as shown in figure [17]

IV. UNITS OF SPEECH FOR PUNJABI LANGUAGE

The syllable comprises vowel and consonants. The presence of vowel is must in a syllable. The vowel is the nucleus, presence of consonant is optional. Vowel (V) is always the nucleus part and the left part is onset and the right part is coda that is consonant.

The seven types of syllables recognized in Punjabi language are as follows:

V, VC, CV, VCC, CCVC, CVCC

There are thirty eight consonants, ten non-nasal vowels and same number of nasal vowels in Punjabi language. Consonants can appear with vowels only. Following are the list of consonants in Punjabi language:

\[ \text{V, VC, CV, VCC, CCVC, CVCC} \]

List of Non-Nasal Vowels:

\[ \text{ਕੀ ਟੀ ਟੇ ਜੀ ਅੰ ਅਂ ਹੀ ਹੀ} \]

The number of nasal vowels is same as non-nasal ones and is represented by Bindi or Tippi over the Non-Nasal Vowels.
V. REPRESENTATION OF SPEECH

Traditionally, the information in speech signal is represented in terms of features derived from Fourier analysis: Fourier transformation, Fast Fourier transformation, discrete fourier transformation, or Wavelets. The key difference between fourier transform and wavelets transform is that wavelet transform is a multi-resolution transform as it allows a form of time-frequency analysis. When using the Fourier transform the result is a very precise analysis of its frequency contained in the signal, but no information about when certain features occurred and about the scale characteristics of the signal. Scale is similar to frequency. It is a measure of the amount of detail in the signal. Small scale means coarse details and large scale means fine details. The information in speech signals can be represented in terms of features derived from short-time Fourier analysis. The information in the short-time FT phase function can be extracted by processing the negative derivative of the FT phase, i.e., the group delay function [7].

$$H(\omega) = H_1(\omega) \cdot H_2(\omega)$$

(1)

Group delay function $\tau(\omega)$ can be represented as $\tau(\omega) = \partial \arg (H(\omega))/\partial \omega = \tau_1(\omega) + \tau_2(\omega)$

(2)

The equation (1) shows the multiplicative property of magnitude spectra where as equation (2) is in group delay domain it becomes an addition. The group delay spectrum has been declared better due to its additive property over magnitude spectra. It was observed that in case of the magnitude spectra the peaks are clearly visible, but the peaks are not resolved in a system where the two poles are combined together [6]. The research shows the disadvantage of multiplicative property of magnitude spectra. In case of group delay spectra the peaks and valleys are better resolved when the signal is in minimum phase [6].

VI. CONCLUSION

In this review, we have discussed the fundamentals of speech recognition and its recent progress is investigated. Speech recognition has been in development for more than 50 years, and has been entertained as an alternative access method for individuals with disabilities for almost as long. Punjabi language deserves attention in this highly growing field of Automatic speech recognition. In this paper, the efforts made by various researchers to develop automatic speech recognition systems for most of the Indo-Aryan languages, have been analysed.
