Computational Solution of Two-Point Boundary Value Problem by Quadrature method in terms of Liouville-Green Transformation

Ch.Baby Rani, J. Venkata Brahman, K. Sharath Babu

Abstract: In this research paper we are selected a two-point edge value problem of singular perturbation with Dirichlet type of margin conditions. The selected differential equation is transformed into the required form by using a Liouville – Green transformation. Then the computational process has been implemented for solving the two-point-boundary line value problem of singular perturbation with either right or left end frontier layer in the specific interval [0,1]. The transformation reduces the mathematical complexity with some assumptions and applied numerical integration method to get the computations for different choices of the perturbation parameter, which is very near to zero. In the present research problem, we have observed the uniform convergence in the computational solution in the regular region and some chaotic behavior near the periphery layer region. We are implemented this method for several linear differential equations and observed that the numerically obtained results are validated with literature.

KEYWORDS: Singular Perturbation, Perturbation parameter, Quadrature, state line narrow region, Liouville-Green Transform, numerical solution.

I. INTRODUCTION

Differential equations occur quite often in the mathematical modeling of physical problems in various disciplines of science, technology and engineering. Since exact solutions for most of these problems are not available, a resort to the approximation methods for getting the solution of such problems is unavoidable. The availability of the high-speed digital computers has made it possible to take such a task when the approximation method involves numerical computation using FDM AND FEM methods. The problems of singular perturbation have found solutions very frequently in the great world of Fluid mechanics, Fluid dynamics, Chemical engineering, Boundary layer phenomena, reaction-diffusion processes, Aerodynamics and Geophysics.

Two-point boundary singularly perturbation possess the boundary layers and/or interior layers (at which the solution become more rapid) either end points or a few inner points with width O (1 as ε → 0). Recently, the researchers have proposed variety of special methods for providing the most plausible solution i.e as near as to the exact solutions using numerical solutions. Among them, one particular method is there to divide the interval into small meshes with equal or unequal width by solving asymptotic expansions of the inner and outer regions such that the constants can be determined by giving a uniform valid solution. Usually, the problems of inner region can be obtained by considering the actual problem with the help of scale change in independent variables. Such type of methodologies and their modifications have been applied successfully for the solution of enormous linear and nonlinear problems of singular perturbation. Of course, triumph of validation of the technique depends on setting up appropriate scaling and/or transformation to state dependent as well as independent variables.

The excellent article given by J. Kevorkian, J.D. Cole [5] resulted the scholarly outcome of solution of the problem with singular perturbation; and their solution methodology starting from Prandtl’s paper [9] on problem of boundary layers in fluid dynamics.

Further, one can refer to the theory and analysis of singular perturbation problems in the literature: A.M. Il’in [1], Bender and Orszag [2], L.E. El’sgol’ts’ etal. [3], P.W. Hemker etal. [4], Kevorkian and Cole [5], Nayfeh [6], and O’Malley [7, 8].

In the present study, singularly perturbed two-point boundary second order problem with right end boundary layer using Liouville-Green transform & numerical quadrature; and we have obtained asymptotic and computational solutions. We have demonstrated some illustrations for validity of this method.

II. LIOUVILLE-GREEN TRANSFORMS

Let us consider present process (proposal) for exceptionally perturbed two-point limit value problems with right –end boundary narrow region of the principal interval. Particularly, we have defined a coarse group of outstanding perturbation difficulty of the non-homogeneous form as follows:

\[ \varepsilon y'' - f(x) y'(x) - g(x) y(x) = h(x), x \in [0,1] \]

With the boundary conditions

\[ y(0)=\alpha \text{ and } y(1)=\beta \] (2)

Where \( \varepsilon \) is very small (0 < \( \varepsilon < 1 \)); \( \alpha, \beta \) are known values of constants; And \( f(x), g(x) \) are continuously differentiable functions in the interval [0,1]. The coefficient of \( y'(x) \) is depressing and non-zero in the interval [0,1].
Computational Solution of Two-Point Boundary Value Problem by Quadrature method in terms of Liouville-Green Transformation

\[-\varepsilon y'' + f(x)y' + g(x)y = h(x), x \text{ is a point in the closed interval } [0,1] \]

Let us consider the Liouville–Green transforms with usual functions \( z, \varphi(x), v(z) \) be

\[ z = \varphi(x) = \frac{1}{\varepsilon} \int f(x) \, dx \tag{4} \]

\[ \Phi(x) = \varphi'(x) = \frac{1}{\varepsilon} f(x) \tag{5} \]

In equation (4) the integral can be evaluating by using numerical quadrature method.

### III. EVALUATION OF THE NUMERICAL INTEGRAL:

In equation (4) Select the starting point as \( x = 0 \) and the terminal point as \( x_i+1 \) and divide the interval in to subintervals such that in each subinterval the total number of entry values are multiples of 2. Now applying the Simpson 1/3rd rule in each subinterval in \([0,1]\) we have

\[
\int_{x_{i-1}}^{x_i} f(x) \, dx = \frac{h}{3} \left[ p_{i-1} y_{i-1} + \frac{\delta}{h} y_i + 4 p_i y_i - \frac{\delta}{h} y_{i-1} + \frac{\delta}{h} y_{i+1} + \frac{\delta}{h} y_{i-1} + \frac{\delta}{h} y_{i+1} + 2 q_i y_{i+1} + 2 q_{i-1} y_{i-1} + 4 q_i y_i + 2 r_i + 4 r_i + 2 r_{i-1} \right] \tag{6}
\]

Where

\[
p(x) = \frac{-2\varepsilon}{2\delta^2 + \delta^2} f(x) \]

\[ q(x) = \frac{2\varepsilon}{2\delta^2 + \delta^2} b(x) \]

\[
[-1 - \frac{2p_{i-1}}{3} \frac{\delta}{h} y_{i-1} + \frac{\delta}{h} y_i + \frac{2p_i}{3} \frac{\delta}{h} y_{i+1} - \frac{\delta}{h} y_{i-1}] \]

After perforating the interval integration in each sub-interval with the uniform step width select the transformation.

\[ v(z) = y(x) \Phi(x) \tag{9} \]

According to (9), with the usual calculus we obtain

\[
dv = \frac{1}{\Phi(x)} \frac{d\Phi(x)}{dx} f(x) \frac{d\Phi(x)}{dx} y(x) \tag{10} = \Phi''(x) \frac{d\Phi(x)}{dx} y(x) \tag{11} \]

From (3), (9), (10) & (11), and we can obtain

\[
e^{-\varepsilon z^2/2} + \left( \frac{2e^{\varepsilon z^2/2} f'(x)}{\phi'(x)} - \frac{\varepsilon y'(x)}{\phi(x)} f(x) \right) \frac{d\phi(x)}{dz} \frac{d\phi(x)}{dz} + \frac{2e^{\varepsilon z^2/2} f'(x)}{\phi'(x)} - \frac{\varepsilon y'(x)}{\phi(x)} f(x) = \frac{\phi''(x)}{\phi(x)} v(z) \]

where \( C_1, C_2 \) are the uninformed constants. From

\[
\text{(4) - (6), we can obtain the asymptotic solutions of discrepancy equations}
\]

\[
y(x) = \frac{\phi(z)}{\phi(x)} = \frac{\varepsilon f(z)}{f(x)} = \frac{\varepsilon}{f(x)} \left( C_1 + C_2 e^{\frac{\delta}{2h} f(x) dx} \right) \tag{15}
\]

where \( C_1, C_2 \) are two arbitrary constants.

The approximate solutions \( v(z) \) of (10) will be follows:

\[
v(z) = C_1 v_1 + C_2 v_2 \tag{14}
\]

everywhere. So the right offer side of Equation (9) not vanishes but close to zero. Therefore, we have an assumed approximation

\[
\frac{d^2 v}{dz^2} - \frac{\varepsilon^2}{2h} \frac{d^2 \phi}{dz^2} o(1) + \frac{1}{\phi} \left[ \frac{\delta p_{i-1}}{3} y_{i-1} + \frac{\delta p_i}{3} y_i + \frac{\delta p_{i+1}}{3} y_{i+1} - \frac{\delta p_{i-1}}{3} y_{i-1} \right]
\]

In the above integral we apply the numerical integration method mentioned in Equation (8) (8)

Then the above TwoPointBoundary value problem (13) possesses the following asymptotic solution:

\[
y(x) = C_1 + C_2 \frac{1}{f(x)} \text{ for } dx \tag{16}
\]

\[
\text{Where} C_1, C_2 \text{ can be evaluated. With the specified conditions. Using (14) & (15)}
\]

### NUMERICAL EXAMPLES:

Consider a Singular pertubation problem (non-homogeneous) as follows:

\[
(I)\ \text{satisfying } 0 < \varepsilon < 1 \text{ and the right offer side of Equation(9) not vanishes but close to zero. Therefore, we have an assumed approximation}
\]

\[
\frac{d^2 v}{dz^2} - \frac{\varepsilon^2}{2h} \frac{d^2 \phi}{dz^2} o(1) + \frac{1}{\phi} \left[ \frac{\delta p_{i-1}}{3} y_{i-1} + \frac{\delta p_i}{3} y_i + \frac{\delta p_{i+1}}{3} y_{i+1} - \frac{\delta p_{i-1}}{3} y_{i-1} \right]
\]

\[
v(z) = C_1 v_1 + C_2 v_2 \tag{14}
\]

\[
\text{Everywhere. So the right offer side of Equation (9) not vanishes but close to zero. Therefore, we have an assumed approximation}
\]

\[
\frac{d^2 v}{dz^2} - \frac{\varepsilon^2}{2h} \frac{d^2 \phi}{dz^2} o(1) + \frac{1}{\phi} \left[ \frac{\delta p_{i-1}}{3} y_{i-1} + \frac{\delta p_i}{3} y_i + \frac{\delta p_{i+1}}{3} y_{i+1} - \frac{\delta p_{i-1}}{3} y_{i-1} \right]
\]

In the above integral we apply the numerical integration method mentioned in Equation (8) (8)

Then the above TwoPointBoundary value problem (13) possesses the following asymptotic solution:

\[
y(x) = C_1 + C_2 \frac{1}{f(x)} \text{ for } dx \tag{16}
\]

\[
\text{Where} C_1, C_2 \text{ can be evaluated. With the specified conditions. Using (14) & (15)}
\]

\[
\text{NUMERICAL EXAMPLES:}
\]

Consider a Singular perturbation problem (non-homogeneous) as follows:

\[
(I)\ \text{satisfying } 0 < \varepsilon < 1 \text{ and the right offer side of Equation(9) not vanishes but close to zero. Therefore, we have an assumed approximation}
\]

\[
\frac{d^2 v}{dz^2} - \frac{\varepsilon^2}{2h} \frac{d^2 \phi}{dz^2} o(1) + \frac{1}{\phi} \left[ \frac{\delta p_{i-1}}{3} y_{i-1} + \frac{\delta p_i}{3} y_i + \frac{\delta p_{i+1}}{3} y_{i+1} - \frac{\delta p_{i-1}}{3} y_{i-1} \right]
\]

In the above integral we apply the numerical integration method mentioned in Equation (8) (8)

Then the above TwoPointBoundary value problem (13) possesses the following asymptotic solution:

\[
y(x) = C_1 + C_2 \frac{1}{f(x)} \text{ for } dx \tag{16}
\]

\[
\text{Where} C_1, C_2 \text{ can be evaluated. With the specified conditions. Using (14) & (15)}
\]

\[
\text{NUMERICAL EXAMPLES:}
\]

Consider a Singular perturbation problem (non-homogeneous) as follows:
\[ \varepsilon y''(x) + y'(x) = 2x + 0.999, \quad 0 \leq x \leq 1 \]

with \( y(0) = 0 \) and \( y(1) = 1 \)

The exact solution is given by

\[ y(x) = x(x + 1 - 2\varepsilon) \left( 1 - \frac{1}{1 + \varepsilon} \right) \]

The computational results are carried out by using the Liouville-Green Transform & Numerical quadrature method. The obtained results were tabulated in Table 3.1 (a&b) for \( \varepsilon = 10^{-3}, 10^{-4} \) respectively.

\( \text{(a)} \ \varepsilon = 10^{-3}, h = 0.01. \)

Table 3.1 (b)

Example 3.2. Consider the below singular perturbation equation

\[ \varepsilon y'' - y' = e^{-x}, x \in [0, 1] \]

With \( y(0) = 1 \) and \( y(1) = 0. \)

At \( x = 1 \) the exact solution using analytical method is

\[ Y(x) = \left( \frac{e^{(x-1)/\varepsilon} - 1}{e^{-1/\varepsilon} - 1} \right) \]

by applying the method, we encompass

\[ f(x) = 1, \ g(x) = 0, \ \alpha = 1, \beta = 0 \]

\[ y(x) \approx \frac{1 - (e^{(x-1)/\varepsilon})}{1 - (e^{-1/\varepsilon})} \]

The computed results are revealed in Tables 1 and 2 for \( \varepsilon = 10^{-3} \) and \( 10^{-4} \) respectively. Numerically computed results show the resolution and accuracy resolution for dissimilarities of x.

Table 1. Computed results for example 3.1 with \( \varepsilon = 10^{-3}, h = 0.001 \)

IV. CONCLUSION

In this research work we are implemented the numerically developed algorithm for solutions of exceptionally worried two peak edge value problems with right end margin coat under the hypothesis that $f(x)$ $\equiv 0$ on the entire intermission $[0,1]$. While calculating the integration values we are applied numerical quadrature method i.e the occupation $f(x)$ has same sign on the entire interval $[0,1]$. This manner is superior on mainframe performance. The numerically obtained results reveals the good approximation with the closed form solutions by means of reasonable good accuracy. For obtaining all the numerical results, C language code has been implemented.
