Finite Element Method For The Parametric Exploration Of Domestic Composite Liquid Petroleum Gas Cylinder With Steel

CH V K N S Moorthy, V Srinivas, K Raghu Ram Mohan Reddy

Abstract: Conventional Steel Cylinders used for LPG cylinder for domestic applications are not manufactured in a single joint but are welded. While composite cylinders are manufactured in a single joint, Composite components cannot be welded like the steel cylinder. Composite Cylinders are winded using Filament Winding technique. Compared to Steel Cylinders, Composite Cylinders are costlier. Composite cylinders are safer than steel cylinder. Composite Cylinders due to a rubber lining inside, they are 100% leak proof. If mass production of composite cylinders are done then the cost may get reduced. This paper summarizes the design and analysis of the manufacturing of Liquid petroleum gas (LPG) Cylinder using Glass Fibre Reinforced Plastic (GFRP) material. Further, the stresses and deformations that may develop due to internal pressure loading on the LPG Cylinder with GFRP material are to be analysed. Hence finite element analysis is applied with ANSYS software to simulate the corresponding analysis. Then the parametric comparative analysis of the LPG Cylinder with steel and GFRP material is also carried out assuming hemispherical end dome and considering cylinder without end frames. A significant saving in the weight of the LPG Cylinder, significant increase in the deformation and volumetric strain is observed with GFRP material against steel.

Keywords: Finite Element Method, GFRP, Liquefied Petroleum Gas (LPG), Pressure Vessel, Steel Vs GFRP.

1. INTRODUCTION

Liquefied petroleum gas (LPG) is a mixture of butane and propane gases stored under pressure, usually in steel cylinders. LPG is heavier than air, non-toxic and odorless. A smelling agent is added to aid users to detect leaks. LPG is a safe, economical and convenient fuel as it has high calorific value (13.8 kWh/kg, which is equivalent to 13.8 units of electricity), provides instantaneous heat, is easy to ignite and clean-burning and is very portable. LPG is stored and handled as a liquid when under pressure inside a L-P-Gas container. When compressed moderately at normal temperature, it becomes liquid. When gas is withdrawn, the pressure drops and the liquid reverts to gas. This means that it can be transported and stored as liquid and burnt as gas. The expansion ratio of gas liquid is 270:1 at atmospheric pressure.

It is expansion factor which makes LP-Gas more economical to transport and store large quantities of gaseous fuel in a small container. LPG appliances include: stoves/ovens, grills, heaters (portable and fixed), instantaneous water heaters, lamps (portable and fixed), refrigeration and welding plant, and Bunsen burners. Appliances are designed to operate both at an unregulated high pressure (e.g. CADAC (or similar) type of camping appliances) and at a lower pressure controlled by a regulator mounted on the gas storage cylinder. High pressure and low-pressure appliances are not interchangeable. Most households use gas appliances with a small dedicated gas cylinder, rather than a reticulated system of gas piping and fixed storage cylinders. Many researchers have studied the analysis of LPG cylinder using composite materials using various commercial softwares [1-3] for the comparison of stress, strain and structure. It is shown that the stable angle of inclination of the fibres, where no strain-induced fibre rotations occur, deviates from the so-called ‘ideal’ fibre angle predicted by netting analysis by an amount that depends on the matrix-to-reinforcement-stiffness ratio [4]. But any pressure vessel made up of composite material like GFRP should be analysed for various parameters related to the manufacturing procedure of the cylinder unlike conventional steel cylinder [5]. Various researchers have published outcomes mentioning corrosion factors of the composites [21], the fibre orientations and their effect on the result of the composites [22] and Electro chemical corrosion effects of composites [25]. The modelling of composites and analysis aspects were published in detail [23] for the basic lead of this research, theoretical modelling was mentioned for Nano fluids [24] which was taken as a direction for the composites with sufficient improvisations. The concepts and features for coatings were also studied [26] before starting this research for understanding any similarities and possible inclusions in the proposed research.

The analysis of LPG domestic cylinder was published using Classical lamination theory [19] and the calculations for various parameters like metallic boss, angle variation at dome and tip radius were explained in detail [20] for the initiation of this analysis. Considering those research outcomes published in the mentioned literature, this paper deals with various simulation analysis results of GFRP cylinder in comparison with that of steel.

III. PARAMETRIC ANALYSIS OF GFRP CYLINDER WITH STEEL WHEN USED FOR THE LPG DOMESTIC GAS CYLINDER

A comparative parametric analysis is done between the steel and GFRP materials for the domestic LPG gas cylinder assuming hemispherical end dome and considering cylinder without end frames. The material and design input data are tabulated in table 4.

\[ \sigma_H = \frac{PD}{2t} \]  

(1)

\[ \sigma_L = \frac{PD}{4t} \]

The following equations are used in calculating the parameters to be compared in deciding the utilization of GFRP to steel

Material volume required = volume of outer pressure vessel – volume of inner pressure vessel = (Volume of Cylinder + Volume of sphere)-(Volume of Cylinder+ Volume of sphere)

\[ V_R = V_o - V_i = (V_c + V_s)_o - (V_c + V_s)_i \]

(3)

Mass of the LPG Cylinder

\[ m = \rho V \]

(4)

Longitudinal Deformation

\[ LD = \frac{pdL(0.5 - \nu)}{2tE} \]

(5)

Change in diameter

\[ \Delta D = \frac{pd^2(1 - 0.5\nu)}{2tE} \]

(6)

Volumetric strain

\[ \varepsilon_v = 2(\frac{\delta l}{d} + \frac{\delta l}{l}) \]

(7)

Change in volume = Volumetric strain \times volume of pressure vessel

\[ \Delta V = \varepsilon_v \times V \]

(8)

IV. RESULTS AND DISCUSSIONS

A. Results of FEA using ANSYS

Modeled the parts like Polar Metallic boss(Brass material), Rubber liner(blow moulding process), Nozzle (machined from brass rods), Cylinder (fabricated using GFRP by filament winding process) and Cylinder casing as well as assembly and the finite element analysis is carried out using ANSYS software. The various stages of modelling and analysis are shown in the figures 1 to 12.

V. CONCLUSIONS

The analysis of LPG cylinder using GFRP composite material and its comparison with that of steel metallic material is carried out using netting analysis, classical lamination theory and finite element analysis. The following conclusions have been drawn:

1. The composite LPG cylinder designed is meeting the expected stipulated maximum operating pressure.
2. The new method proposed for analysis of filament wound composite cylinder is worked out to be efficient in accurately predicting the structural response.
3. The FE results and analytical results are in close agreement.
4. The design stresses are within safe limits.
5. Based on structural analysis, fibre stresses are within safe limits and weight saving can be achieved by 75% against the metallic cylinder. In future LPG
composite cylinders can be fabricated and test can be performed to see the design margins.

ACKNOWLEDGMENT

It is optional. The preferred spelling of the word “acknowledgment” in American English is without an “e” after the “g.” Use the singular heading even if you have many acknowledgments. Avoid expressions such as “One of us (S.B.A.) would like to thank ...” Instead, write “F. A. Author thanks” “Sponsor and financial support acknowledgments are placed in the unnumbered footnote on the first page.
