Analysis of Five Phase Inverter with different SVPWM Switching Techniques for Induction Motor Drive

D. Raja, G. Ravi

Abstract: Multi-phase Induction motor drives (MPIMD) with numerous advantages dominates three-phase drives and emerges as a potential contender and viable solution for the high power electric drive applications. When multi-phase AC drives fed from voltage source inverters (VSIs) requires a suitable PWM method of control. This paper investigates the performance of 5-\$\phi\$ induction motor drive with various space vector PWM (SVPWM) techniques. First, a 5-\$\phi\$ VSI model is presented in terms of space vectors. Next, modified SVPWM switching techniques are introduced based on medium, large and the combination of medium and large vectors, which provide its working with reduced %THD in the output voltages. The proposed scheme uses the full DC bus voltage, and the output response superior with low lower order harmonics than the conventional SVPWM methods. The performances of the 5- ϕ VSI fed IM drive tested with various switching techniques, and the results observed in terms of harmonic contents present in the output voltage waveform. MATLAB/Simulink software results included in this paper to show and verify the theoretical concepts.

Index Terms: SVPWM, five-phase VSI, five-phase induction motor, total harmonic distortion

I. INTRODUCTION

In general, multi-phase systems have many advantages, and they are used in applications such as automotive industry, aeronautics and electric power generation due to a variety of benefits provided by multi-phase drives over $3-\varphi$ drives. [1]. In the case of even number phases, the poles are coinciding with each other, and it will reduce the motor performance. So, odd number phases are preferred over even number phases [2]-[3]. Also, the output power of a $5-\varphi$ system is greater than that of the $3-\varphi$ system. This has attracted the interest in the development of multi phase machines [4], [5].

The broad choice of switching techniques can be used for the VSI to produce the expected output [6]-[9]. The techniques start with sin triangle PWM, conventional SVPWM, and modified SVPWM. SVPWM technique is more suitable for multiphase VSI, and the no. of vectors increase with the no. of a levels and no. of phases (i.e., 'm' is the no. of level of VSI and 'n' is the no. of phases) [10], [11].

A 2 level VSI has 32 vectors represented into d1-q1 & d3-q3 subspaces. All subspaces are a source of lower order harmonics except the d1-q1 subspace. The switching techniques proposed in [12] can eliminate the harmonics

present in d3-q3. In addition, this method can generate a sinusoidal phase voltage waveform. There are few SVPWM techniques proposed in [13]-[16] to minimize the switching losses of a 5-\$\phi\$ inverter.

The SVPWM with modified switching scheme is proposed in this paper for the 5- ϕ VSI fed IM drive. The MATLAB/ Simulink is used to construct the system. The performances of the proposed techniques are compared with conventional SVPWM technique.

II. MODELING OF FIVE PHASE INDUCTION MOTOR

A Mathematical model can be represented for an induction motor. The 5- ϕ system variables are transformed into 2- ϕ variables in d-q plane rotating with synchronous speed. The displacement between two phases is 72 degrees, and the number of phases must be the same before and after the transformation. The relationships between 5- ϕ and 2- ϕ variables are as follows.

$$V_{dq}^s = K_S \ V_{abcde}^s \qquad i_{dq}^s = K_S \ i_{abcde}^s \qquad \Psi_{dq}^s = K_S \ \Psi_{abcde}^s \qquad (1)$$

$$\begin{array}{lll} V^r_{dq} \! = \! K_r \, V^r_{abcde} & i^r_{dq} \! = \! K_r \, i^r_{abcde} & \Psi^r_{dq} \! = \! K_r \, \Psi^r_{abcde} \\ Where. \end{array} \tag{2}$$

where,
$$K = \sqrt{\frac{2}{5}} \begin{bmatrix} 1 \cos\left(\frac{2\pi}{5}\right) \cos\left(\frac{4\pi}{5}\right) & \cos\left(\frac{4\pi}{5}\right) & \cos\left(\frac{2\pi}{5}\right) \\ 0 \sin\left(\frac{2\pi}{5}\right) & \sin\left(\frac{4\pi}{5}\right) & \sin\left(\frac{4\pi}{5}\right) & \sin\left(\frac{2\pi}{5}\right) \\ 1 \cos\left(\frac{4\pi}{5}\right) & \cos\left(\frac{8\pi}{5}\right) & \cos\left(\frac{8\pi}{5}\right) & \cos\left(\frac{4\pi}{5}\right) \\ 0 \sin\left(\frac{4\pi}{5}\right) & \sin\left(\frac{8\pi}{5}\right) - \sin\left(\frac{8\pi}{5}\right) & -\sin\left(\frac{4\pi}{5}\right) \\ \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \end{bmatrix} (3)$$

 $^{\circ}$ K' is the 5-φ induction machine decoupling transformation matrix given in equation 2. The 5-φ machine is represented in the d-q-x-y-o arbitrary plane. The d-q components are responsible for power generation, fluxes and torque production in the machine. System losses are accounted by x-y components, and the reason for zero components being used is to show unchanged in the system. The 5-φ IM is modeled in the MATLAB Simulink, and the characteristics responses are obtained.

Essential machine model equations for stator sides and rotor sides in stationary reference frame are represented as follows:

$$\begin{array}{l} V_{ds} = R_{s}i_{ds} + p\Psi_{ds} \\ V_{qs} = R_{s}i_{qs} + p\Psi_{qs} \\ (4) \\ \Psi_{xs} = L_{ls}i_{xs} \end{array}$$

$$\begin{split} \Psi_{ys} &= L_{ls} i_{ys} & (5) \\ V_{dr} &= R_r i_{dr} + p \Psi_{dr} & V_{qr} &= R_r i_{qr} + p \Psi_{qr} \\ \Psi_{xr} &= L_{lr} i_{xr} & \Psi_{yr} &= L_{lr} i_{yr} & (7) \end{split}$$

$$\Psi_{xr} = L_{lr} i_{xr} \qquad \qquad \Psi_{yr} = L_{lr} i_{yr} \qquad (7)$$

Flux Linkage equations for stator and rotor sides are expressed as follows:

$$\Psi_{xs} = L_{ls}i_{xs} \qquad \qquad \Psi_{xr} = L_{lr}i_{xr} \qquad (8)$$

$$\Psi_{ds} = (L_{ls} + L_m)i_{ds} + L_mi_{dr}$$

$$\Psi_{qs} = (L_{ls} + L_{m})i_{qs} + L_{m}i_{qr}$$
 (9)

$$\Psi_{dr} = (L_{lr} + L_m)i_{dr} + L_m i_{ds}$$

$$\Psi_{qr} = (L_{lr} + L_m)i_{qr} + L_mi_{qs}$$
 (10)

Where,
$$L_{s} = L_{ls} + L_{m}$$
 $L_{r} = L_{lr} + L_{m}$ (11)
 $\Psi_{ys} = L_{ls}i_{ys}$ $\Psi_{yr} = L_{lr}i_{yr}$ (12)

$$\Psi_{vs} = L_{ls} i_{vs} \qquad \Psi_{vr} = L_{lr} i_{vr} \qquad (12)$$

The equation for torque can be denoted as:

$$T_{e} = PL_{m}(i_{dr}i_{qs} - i_{ds}i_{dr})$$
 (13)

$$w_{r} = \int \frac{P}{2I} (T_{e} - T_{L})$$
 (14)

III. TWO-LEVEL FIVE-PHASE VSI

Multi-phase IM drives used for variable applications. The conventional multiphase VSI does not suitable for this application owing to the high amount of harmonics presented in the voltage waveforms. A space vector concept is used with a modified switching sequence to reduce the harmonics and also helps to maximize the fundamental voltage.

Fig.1 shows the circuit diagram for 5-\$\phi\$ VSI fed 5-\$\phi\$ IM drive comprises ten power switches, two switches per leg. The pole voltage is equal to Vdc when the upper switch is ON and it is zero when it is OFF. To avoid the direct short circuit of same leg switches, they switched opposite to each other.

Phase to neutral voltages (Va \sim Ve) of 5- ϕ VSI can be expressed in terms of inverter pole voltages as given in equation (15) and (16) [12].

$$V_{j} = \frac{4}{5}V_{j} - \frac{1}{5}\sum_{i,i\neq j}^{5}V_{j}, \text{ if } j < 5$$
 (15)

$$V_{j} = \frac{4}{5}V_{j} - \frac{1}{5}\sum_{i,i\neq j}^{4}V_{j}, \text{ if } j = 5$$
 (16)

In general, a 5-\phi 2-level VSI has 32 combinations of switching states (ie., 2n, where n is the number of phases) and can be represented in two space vector planes (d1-q1 and d3-q3) includes thirty active and two zero vectors.

Binary numbers are used to represent the states on each space vectors. Bit '0' represents that the lower switch is ON while a bit '1' represents that the upper switch is on. The three coordinated decagons formed by 30 active vectors originate at the 2 zero vectors. Inner, middle and outer decagons magnitudes are 0.2472, 0.4, and 0.6472.

Fig 2 and Fig. 3 shows the space vector representation in a d-q plane. The phase sequence in d1q1 is ABCDE while in d3q3 it is ACEBD. The middle decagon is the same in both subspaces while the inner and outer decagons are interchanged between d1q1 and d3q3.equation (17) and (18) represents the 5-φ inverter voltage in a two-phase d-q plane. The value of a, a2, a3, & a4 is given in equation (19) to (22).

$$V_{d1q1} = \frac{2}{5} V_{dc} [V_a + aV_b + a^2 V_c + a^3 V_d + a^4 V_e]$$
 (17)

$$V_{d1q1} = \frac{2}{5}V_{dc}[V_a + aV_b + a^2V_c + a^3V_d + a^4V_e]$$

$$V_{d3q3} = \frac{2}{5}V_{dc}[V_a + aV_c + a^2V_e + a^3V_b + a^4V_d]$$
(18)

$$a = \cos\frac{2\pi}{5} + \sin\frac{2\pi}{5} \tag{19}$$

$$a^2 = \cos\frac{4\pi}{5} + \sin\frac{4\pi}{5} \tag{20}$$

$$a^3 = \cos\frac{4\pi}{r} - \sin\frac{4\pi}{r} \tag{21}$$

$$a^4 = \cos\frac{2\pi}{5} - \sin\frac{2\pi}{5} \tag{22}$$

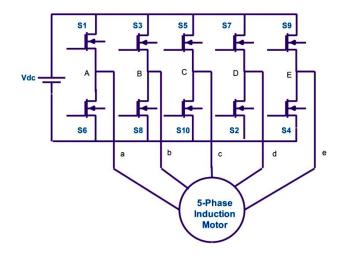

Fig. 1 5-φ VSI fed 5-φ IM drive

IV. SVPWM SWITCHING SCHEMES FOR 5-Ф VSI

A. Switching Scheme I: Using Medium Vectors in (d₁q₁ plane)

The medium decagon of a d_1q_1 plane is considered in this elementary space vector (SV) modulation switching scheme for 5-φ VSI. The switching vector rotates in an anti-clockwise direction starting from V₁₆ until V₃₀ is reached as shown in Fig. 2. The equations (23), (24) & (25) used to calculate the conduction time in each switching state. Fig. 4 (a) & (b) shows the upper IGBT conventional and modified switching pattern in each phase and the respective switching vector shown in Fig. 5 (a). In conventional switching scheme, the switching vectors start from 0, 16, 29, 31, 31, 29, 16, and 0 for one switching cycle T_s in sector I. while the zero switching vector 31 is eliminated in modified switching scheme. Fig. 5(b) & (C) shows the modulating signals for conventional and modified switching schemes.

The conduction time of each switching state is calculated by using the following expressions.

$$t_{am} = \frac{|V_{ref}|\sin\left(\left(K_{5}^{\pi}\right) - \theta\right)}{V_{m}\sin\left(\frac{\pi}{5}\right)} t_{s}$$
 (23)

$$t_{bm} = \frac{|V_{ref}|\sin\left(\theta - \left((K-1)\frac{\pi}{5}\right)\right)}{V_{m}\sin\left(\frac{\pi}{5}\right)}t_{s}$$
 (24)

$$t_0 = \frac{t_s - t_{am} - t_{bm}}{2} \tag{25}$$

Maximum possible fundamental peak voltage of large space vector is

$$V_{\text{max}} = |V_{\text{m}}| \cos \frac{\pi}{10} V_{\text{dc}} = 0.3804 V_{\text{dc}}$$
 (26)

B. Switching Scheme II: Using Large Vectors $(d_1q_1$ plane)

The Space Vectors in the large decagon of d_1q_1 plane are considered. The

switching vector rotates in an anti-clockwise direction starting from V_{25} until V_{17} as shown in Fig. 2. The equations (27), (28) & (29) used to calculate the conduction time in each switching state. Fig. 6 (a) & (b) shows the upper IGBT switching pattern in each phase and the respective switching vector has shown in Fig. 7 (a). In conventional switching scheme, the switching vectors start from 0, 25, 24, 31, 31, 24, 25, and 0 for one switching cycle T_s in sector I. while the zero switching vector 31 is eliminated in modified switching scheme. Fig. 7 (b) & (C) shows the modulating signals for conventional and modified switching schemes.

The following expressions are used to calculate the conduction time t_{al} , t_{bl} and t_{o} .

$$t_{al} = \frac{|V_{ref}|\sin\left(\left(K_{5}^{\pi}\right) - \theta\right)}{V_{l}\sin\left(\frac{\pi}{5}\right)} t_{s}$$
 (27)

$$t_{bl} = \frac{|V_{ref}|\sin\left(\theta - \left((K-1)\frac{\pi}{5}\right)\right)}{V_{l}\sin\left(\frac{\pi}{5}\right)}t_{s}$$

$$t_{0} = \frac{t_{s} - t_{al} - t_{bl}}{2}$$
(28)

$$t_0 = \frac{t_s - t_{al} - t_{bl}}{2} \tag{29}$$

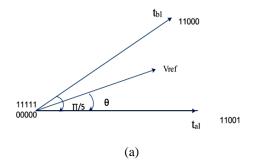

Maximum possible fundamental peak voltage of large space vector is

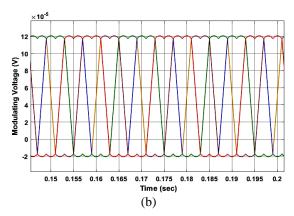

$$V_{\text{max}} = |V_{\text{l}}| \cos \frac{\pi}{10} V_{\text{dc}} = 0.6155 V_{\text{dc}}$$

C. Switching Scheme III: Using combination of medium and Large Vectors (d₁q₁ plane)

Instead of using only two active and two zero vectors, four active and two zero vectors can be used for the five phase VSI. Fig. 8 (a) & (b) shows the upper IGBT switching pattern in each phase and the respective switching vector has shown in Fig. 9 (a). In conventional switching scheme, the switching vectors start from 0, 16, 25,29,31,31,29,25,24,16,0 for one switching cycle T_s in sector I. while the zero switching vectors 31 is eliminated in modified switching scheme. Fig. 9 (b) & (C) shows the modulating signals for conventional and modified switching schemes.

The following expressions are used to calculate the conduction time t_{am} , t_{bm} , t_{al} , t_{bl} and t_{o} .

$$t_a = t_{al} + t_{am} \tag{31}$$

$$t_b = t_{bl} + t_{bm} \tag{32}$$

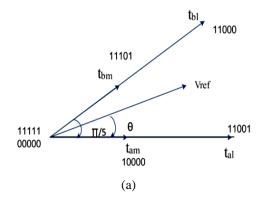

The Maximum possible fundamental peak voltage of combinations of medium and large space vector is

$$|V_{\rm m}|\cos\frac{\pi}{10}V_{\rm dc} \le V_{\rm max} \le |V_{\rm l}|\cos\frac{\pi}{10}V_{\rm dc}$$

V. SIMULATION RESULTS

A MATLAB software simulation is used to determine the effect of SV based switching techniques and to compare the results of various switching techniques such as medium vector, large vector and the grouping of a medium and large vector in d1-q1 subspace. The simulation parameters used for the system are: Vdc=400V, the fundamental output frequency of VSI is 50Hz, switching frequency fs = 5 kHz and the dead time of switches present in the same leg has not been considered. Table 1 lists the simulation parameters of the system, and the performance characteristics are shown in Fig. 10. The phase and line voltage of 5-φ VSI is shown in Fig.10 (a) & (b). The 5-phase induction motor electromagnetic torque is tracking the reference torque command of 3 Nm, 2 Nm and 4.4 Nm at the instants 0.4 sec, 0.8 and 1.3 sec respectively as shown in Fig. 10 (c). The stator and rotor current variations regarding the load changes have been recorded and shown in Fig. 10 (d).

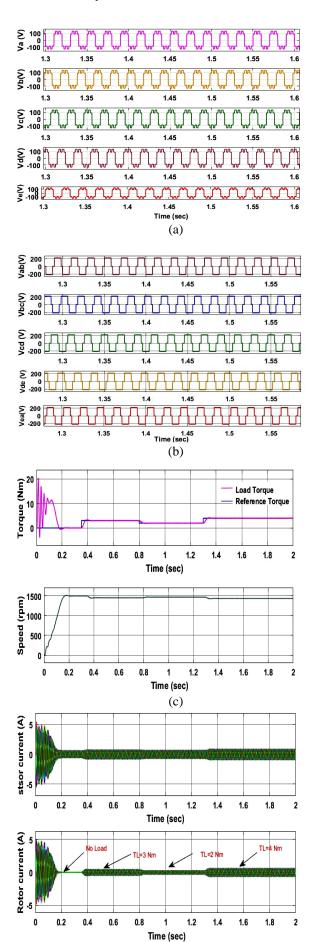

Fig. 10 Performance characteristics of 5-φ SVPWM VSI fed IM Drive (a) Phase Voltage (b) Line Voltage (c) Speed & torque response (d) stator & rotor current

(d)

Table 1
Parameters of 5-♦ VSI fed IM Drive

| Parameters | Values |
|-----------------------------|----------------|
| DC Bus voltage | 400 V |
| Switching frequency | 5 KHz |
| Motor RMS Input Voltage (V) | 220 |
| No. of Phases | 5 |
| Number of Poles (p) | 4 |
| Resistance (stator) | 10.1 Ω |
| Inductance (stator) | 0.833 Henry |
| Resistance (rotor) | $9.854~\Omega$ |
| Inductance (rotor) | 0.782 Henry |
| Mutual Inductance | 0.782 Henry |
| Inertia | 0.0088 |

Two different SVPWM switching schemes are designed for 5-φ SVPWM VSI fed IM drive. The output phase fundamental voltage and total harmonic distortions are considered as the factors to identify the best switching scheme for 5-φ VSI. Also, these two factors are obtained for different values of the modulation index. The fundamental voltage peak is high for the modified SVPWM switching scheme when compared to conventional SVPWM technique as noted from Fig. 11 and Fig.13. The %THD in the phase voltage of 5-φ SVPWM VSI fed IM drive is observed for different modulation index is as shown in the Fig.12 and Fig.14.

From the comparative results of SVPWM switching techniques, the $d_1\text{-}q_1$ large vector switching produces the % THD of 30.09% whereas the conventional SVPWM its value is about 42.14% . Therefore it is inferred that the 5- φ VSI with large vector SVPWM switching scheme gives the optimum results for the output voltage fundamental peak and lower % voltage THD.

VI. CONCLUSION

A 5- ϕ VSI with various SVPWM techniques are presented to improve the power quality of input voltage applied to 5- ϕ IM drive. Use of SVPWM techniques improves the utilization of DC bus voltage when compared to SPWM techniques. This control technique also improves the

fundamental output voltage by 25% greater than the sinusoidal pulse width modulation techniques. This investigation is performed in the MATLAB Simulink for 5- ϕ VSI fed IM drive. The results of fundamental voltage and % THD in the output voltage for different switching schemes in d₁q₁ subspaces are obtained. These comparison result shows that d₁-q₁ large vector switching technique gives the maximum fundamental voltage and lesser %THD in output voltage than other methods.
